

String Reduction

Given a string consisting of letters, 'a', 'b' and 'c', we can perform the following operation: Take any two adjacent distinct characters and replace them with the third character. For example, if 'a' and 'c' are adjacent, they can be replaced by 'b'. Find the smallest string which we can obtain by applying this operation repeatedly?

Input Format:

The first line contains the number of test cases T . T test cases follow. Each test case contains the string you start with.

Constraints:

- $1 \leq T \leq 100$
- The string will have at most 100 characters.

Output Format:

Output T lines, one for each test case, containing the smallest length of the resultant string after applying the operations optimally.

Sample Input:

```
3
cab
bcab
cccc
```

Sample Output:

```
2
1
5
```

Explanation:

For the first case, you can either get $cab \rightarrow cc$ or $cab \rightarrow bb$, resulting in a string of length 2.
For the second case, one optimal solution is: $bcab \rightarrow aab \rightarrow ac \rightarrow b$. No more operations can be applied and the resultant string has length 1.
For the third case, no operations can be performed. So the answer is 5.
